MRI LUMBOSACRAL SPINE

Clinical Notes

Left posterior thigh pain radiating to the left heel and urinary incontinence.

Technique

High field strength MRI of the lumbosacral spine has been performed without contrast.

Findings

The conus is situated at the level of L4 vertebral body and tethered to a large T1 and T2 hyperintense soft tissue mass, measuring at least 121 x 49 x 20 mm in maximum dimension. There is complete fat suppression and no contrast enhancement.

An irregular and enhancing soft tissue mass is seen in the subcutaneous layer at the level of S1, measuring 16 x 16 mm in maximum transaxial dimension, suggestive of a dermal sinus.

There is deformity of the posterior aspect of the conus. No evidence of diastematomyelia.

There is suggestion of extension into the left neural foramen encasement of the left L5 nerve root.

There is also effacement of the left lateral recess with apparent compression of the left S1 nerve root ganglion

No disc protrusion, canal stenosis or nerve root compression.

The SI joints appear within normal limits.

The paravertebral soft tissues appear unremarkable.

CONCLUSION

A large lipoma at the cauda equina, measuring 121 mm in maximum dimension with tethered cord syndrome at L5.

The left L5 nerve root and the left S1 nerve root ganglions are probably compromised.

An irregular and enhancing soft tissue mass is seen in the subcutaneous layer at the level of S1 suggestive of a dermal sinus.
